Introduction to React part -1

Sunday, September 07, 2025
11:00 AM SGT

Building Frontend for a Home Listings Admin App using ReactJS

Agenda

- Wireframing & Prototyping
- LLD & HLD
- Decomposing a Design into components
- File Structure / Folder Hierarchy
- Creating Components
- Building React Application

Remember while building components

1. React components are regular JavaScript functions, but their names must start with a capital letter or they won't work!
2. Without parentheses, any code on the lines after return will be ignored!
3. Components can render other components, but you must never nest their definitions
4. define every component at the top level
5. When a child component needs some data from a parent, pass it by props instead of nesting definitions.

Remember while building components

1. you can create components that are composed of other components, splitting them into different files
2. make them more modular and reusable in other files.
3. Either './Gallery.js' or './Gallery' will work with React
4. A file can have no more than one default export, but it can have as many named exports as you like.
5. How you export your component dictates how you must import it.

Remember while building components

Props with a component

- React components use props to communicate with each other.
- Every parent component can pass some information to its child components by giving them props.

Remember while building components

Props with a component

- React components use props to communicate with each other.
- Every parent component can pass some information to its child components by giving them props.
- If you want to give a prop a default value to fall back on when no value is specified, you can do it with the destructuring by putting = and the default value right after the parameter
- When you nest content inside a JSX tag, the parent component will receive that content in a prop called children
